Project Design Phase
Solution Architecture

Date	4 October 2026
Team ID	
Project Name	Automated Network Request Management in ServiceNow
Maximum Marks	4 Marks

Solution Architecture:

Solution architecture is the process of designing the structure and components of a software system to address business problems using suitable technologies. It describes how the system components interact, manage data, and deliver the required functionality.

The solution architecture for Automated Network Request Management in ServiceNow is designed to simplify and automate the network request lifecycle. It combines standard ServiceNow platform tables with a custom Network Request table to maintain structured and reliable request information.

Users submit network requests through catalog-driven forms by providing details such as request type, access level, business justification, and related network configuration items. Dynamic form logic displays relevant fields based on the selected request type, while mandatory field validation helps maintain data accuracy and compliance.

ServiceNow workflows process the submitted requests, support approval and assignment activities, and maintain request status information. List views help approvers and network support teams monitor requests, tasks, and progress. Reporting capabilities provide visibility into the overall request lifecycle.

Goals of the Solution Architecture

- Solve the business problem: Reduce manual effort in submitting, categorizing, assigning, and tracking network requests.
- Define system structure: Explain how the Service Catalog, request forms, standard tables, custom Network Request table, and workflows interact.
- Describe system behaviour: Show how request validation, dynamic fields, approvals, assignment, and status updates work together.
- Support secure access: Apply appropriate roles and access controls to protect

request information.

- Enable reliable reporting: Maintain structured request data for list views, monitoring, and reports.
- Support future enhancements: Allow additional network request types and workflow rules to be configured as requirements grow.
